A circuit board assembly is provided. The circuit board assembly includes: a first circuit board; a second circuit board; a bracket for supporting the second circuit board; and an interconnect apparatus for a connection and a disconnection of the first circuit board and the second circuit board, wherein the interconnect apparatus includes a first connector disposed on the first circuit board and a second connector disposed on the second circuit board (one is a male connector and the other is a female connector). The circuit board assembly includes a lifting and lowering apparatus for vertically lifting or lowering the bracket so that after the connection the second connector is vertically disconnected from the first connector and after the disconnection the second connector is vertically connected to the first connector. An electronic device having the circuit board assembly is further provided.

FIG. 3

FIG.4

1

CIRCUIT BOARD ASSEMBLY, ELECTRONIC DEVICE HAVING THE SAME, AND LIFTING AND LOWERING APPARATUS THEREOF

This application is based on and claims the benefit of priority from Taiwan Patent Application 100143896, filed on Nov. 30, 2011.

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to circuit board connection and disconnection, and more particularly, to a circuit board/bracket lifting and lowering apparatus, a circuit board assembly having the same, and an electronic device having the same.

2. Description of the Prior Art

A typical electronic system comprises a plurality of electrical connection assemblies including but not limited to circuit boards and related electrical connection assemblies and interconnects. According to the prior art, circuit boards, electrical connection assemblies, and interconnects have electrical terminals for connection with the electrical terminals of the other circuit boards, electrical connection assemblies, and interconnects.

Conventionally, electrical connection assemblies or interconnects has a male connector and a female connector for connection and engagement. If the pins of the male connector are not accurately aligned with the pins of the female connector before the male connector is inserted into the female connector, the assemblies will be likely to be damaged. In particular, if the male connector and/or the female connector are of a great length, including but not limited to Intel's QuickPath Interconnect (QPI) (QPI is a point-to-point interconnect dedicated to a central processing unit (CPU) and adapted to connect a circuit board and another circuit board), there will be a high chance of damaging the assemblies during a jointing process, thereby reducing their service life greatly.

In another aspect, a process of connecting a circuit board and another circuit board by means including but not limited to three QPI requires applying a large mating force and a large unmating force to between the male connector and the female connector to the detriment of a plugging/unplugging process and operation performed by a user.

Accordingly, it is imperative to provide interconnect technology for use with a circuit board to thereby reduce the chance of damaging its pins, extend its service life, and facilitate the user's operation and application.

SUMMARY OF THE INVENTION

The present invention provides, in an embodiment thereof, a circuit board assembly. The circuit board assembly comprises: a first circuit board; a second circuit board; and a bracket for supporting the second circuit board. The circuit board assembly further comprises an interconnect apparatus for a connection and a disconnection of the first circuit board and the second circuit board, wherein the interconnect apparatus comprises a first connector disposed on the first circuit board and a second connector disposed on the second circuit board so as to effectuate a connection and a disconnection of, wherein one of the first connector and the second circuit board is a male connector, and the other one of the first connector and the second circuit board is a female connector. The circuit board assembly further comprises a bracket lifting and lowering apparatus for vertically lifting and lowering the bracket such that after the connection the second connector is verti-

2

cally disconnected from the first connector and after the disconnection the second connector is vertically connected to the first connector.

The bracket has a pair of lateral sides each having thereon a curved groove and a sliding groove. The bracket lifting and lowering apparatus comprises a rotary rod having a pair of end portions each provided with a pivotal pin. The bracket lifting and lowering apparatus further comprises a pair of sliding elements slidably disposed in the sliding grooves, respectively. The sliding elements each have thereon a linear guiding groove and a supporting stand guiding groove of a specific inclination. The rotary rod is pivotally coupled to the bracket by means of the pivotal pins and the curved grooves. The sliding elements are engaged with the bracket by means of the pivotal pins and the linear guiding grooves. The bracket lifting and lowering apparatus further comprises a pair of supporting stands fixed to the first circuit board and slidably disposed in the supporting stand guiding grooves, respectively.

In response to the rotation of the rotary rod in a first direction, the pivotal pins follow a continuum of intersections of each said linear guiding groove and a corresponding one of the curved grooves to thereby allow the sliding elements to undergo a horizontal displacement. The horizontal displacement of the sliding elements is accompanied by a vertical displacement of the bracket and the second circuit board because of joint operation of engagement of the sliding elements with the bracket, the supporting stands fixed to the first circuit board, and the supporting stand sliding grooves of a specific inclination.

The present invention provides, in another embodiment thereof, an electronic device. The electronic device comprises a casing and a circuit board assembly. The circuit board assembly comprises: a first circuit board; a second circuit board; and a bracket for supporting the second circuit board. The circuit board assembly further comprises an interconnect apparatus for a connection and a disconnection of the first circuit board and the second circuit board. The interconnect apparatus comprises a first connector disposed on the first circuit board and a second connector disposed on the second circuit board for a connection or a disconnection thereof. One of the first connector and the second circuit board is a male connector, whereas the other one of the first connector and the second circuit board is a female connector. The circuit board assembly further comprises a bracket lifting and lowering apparatus for vertically lifting and lowering the bracket such that after the connection the second connector is vertically disconnected from the first connector and after the disconnection the second connector is vertically connected to the first connector.

The present invention provides, in yet another embodiment thereof, a lifting and lowering apparatus applicable to a circuit board assembly. The circuit board assembly comprises: a first circuit board; a second circuit board; and an interconnect apparatus for a connection and a disconnection of the first circuit board and the second circuit board. The interconnect apparatus comprises a first connector disposed on the first circuit board and a second connector disposed on the second circuit board for a connection or a disconnection thereof. The circuit board assembly further comprises a bracket for supporting the second circuit board. The bracket has a pair of lateral sides. The lateral sides each have thereon a curved groove and a sliding groove. The lifting and lowering apparatus comprises a rotary rod having a pair of end portions each provided with a pivotal pin. The lifting and lowering apparatus further comprises a pair of sliding elements slidably disposed in the sliding grooves, respectively. The sliding ele-

3

ments each have thereon a linear guiding groove and a supporting stand guiding groove of a specific inclination. The rotary rod is pivotally coupled to the bracket by the pivotal pins and the curved grooves. The sliding elements are engaged with the bracket by the pivotal pins and the linear guiding grooves. The lifting and lowering apparatus further comprises a pair of supporting stands fixed to the first circuit board and slidably disposed in the supporting stand guiding grooves, respectively. In response to the rotation of the rotary rod in a first direction, the pivotal pins follow a continuum of intersections of each said linear guiding groove and a corresponding one of the curved grooves to thereby allow the sliding elements to undergo a horizontal displacement and allow the bracket to undergo a vertical displacement.

Reference throughout this specification to features, advantages, or similar language does not imply that all of the features and advantages that may be realized with the present invention should be or are in any single embodiment of the invention. Rather, language referring to the features and advantages is understood to mean that a specific feature, advantage, or characteristic described in connection with an embodiment is included in at least one embodiment of the present invention. Thus, discussion of the features and advantages, and similar language, throughout this specification may, but do not necessarily, refer to the same embodiment.

Furthermore, the described features, advantages, and characteristics of the invention may be combined in any suitable manner in one or more embodiments. One skilled in the relevant art will recognize that the invention may be practiced without one or more of the specific features or advantages of a particular embodiment. In other instances, additional features and advantages may be recognized in certain embodiments that may not be present in all embodiments of the invention.

BRIEF DESCRIPTION OF THE DRAWINGS

In order that the advantages of the invention will be readily understood, a more particular description of the invention briefly described above will be rendered by reference to specific embodiments that are illustrated in the appended drawings. Understanding that these drawings depict only typical embodiments of the invention and are not therefore to be considered to be limiting of its scope, the invention will be described and explained with additional specificity and detail through the use of the accompanying drawings. In the drawings:

FIG. 1 is a schematic view of an electronic system according to a preferred embodiment of the present invention;

FIG. 2 is an exploded view of the electronic system according to a preferred embodiment of the present invention;

FIG. 3 is a perspective view of a bracket mobile device according to a preferred embodiment of the present invention; and

FIG. 4 is a perspective view of the bracket mobile device according to a preferred embodiment of the present invention.

DETAILED DESCRIPTION OF THE EMBODIMENTS

Reference throughout this specification to “one embodiment,” “an embodiment,” or similar language means that a particular feature, structure, or characteristic described in connection with the embodiment is included in at least one embodiment of the present invention. Thus, appearances of the phrases “in one embodiment,” “in an embodiment,” and

4

similar language throughout this specification may, but do not necessarily, all refer to the same embodiment.

Referring to FIG. 1, there is shown a schematic view of an electronic system 100 according to a preferred embodiment of the present invention, showing a first circuit board 104 and a second circuit board 108 which are electrically coupled to each other. Normally, the electronic system 100 comprises a plurality of electrical connection assemblies and further comprises circuit boards and connector-related assemblies. An electrical circuit-related portion of each circuit board has electrical terminals which are connected to the electrical terminals of another circuit board via electrical connection assemblies or interconnects.

The first circuit board 104 includes but is not limited to a primary circuit board mounted thereon with a first assembly 116. The first assembly 116 comprises one or more integrated circuits or one or more packaged integrated circuits including but not limited to a first central processing unit (CPU). The first assembly 116 further comprises various electromechanical assemblies. The second circuit board 108 includes but is not limited to a secondary circuit board 108 mounted thereon with a second assembly 124. The second assembly 124 comprises one or more integrated circuits or one or more packaged integrated circuits including but not limited to a second central processing unit (CPU). The second assembly 124 further comprises a dynamic random-access memory (DRAM) and various electromechanical assemblies. The first circuit board 104 and the second circuit board 108 are connected by interconnects 136. The interconnects 136 include but are not limited to an QPI, HyperTransport (HT) of Advanced Micro Devices (AMD), or conventional connectors disclosed in the related prior art. Take the QPI 136 as an example, it is provided with a male connector 140 and a female connector 144. Pins (not shown) of the male connector 140 are inserted into and engaged with pin-receiving holes (not shown) of the female connector 144, respectively, as soon as the male connector 140 comes into snap-engagement with the female connector 144. However, according to the prior art, a male connector of the QPI is 12 mm long, whereas a female connector of the QPI is 36.5 mm long; hence, the process of aligning the pins with the pin-receiving holes is susceptible to offset and thus misalignment. As a result, forced engagement causes damage to the pins or pin-receiving holes and shortens their service life.

Referring to FIG. 2, there is shown an exploded view of the electronic system 100 according to a preferred embodiment of the present invention. In a preferred embodiment of the present invention, a lifting and lowering apparatus 200 comprises a handle body 208, a rotary rod 204, and a pair of sliding elements 212. Referring to FIG. 2, the lifting and lowering apparatus 200 further comprises a bracket 216 for supporting the second circuit board 108 and a pair of pivotal pins 214. The pivotal pins 214 are riveted to a pair of end portions 218 of the rotary rod 204. The bracket 216 has a pair of lateral sides 215 each having thereon a curved groove 220 for operating in conjunction with the rotary rod 204 and the pivotal pins 214 (as described in detail below.)

The handle body 208 is intended to be gripped by a user for controlling the vertical displacement of the bracket 216 and the second circuit board 108. The end portions 218 of the rotary rod 204 are pivotally coupled to the bracket 216 by means of the pivotal pins 214 and the curved grooves 220, such that the user can operate the handle body 208 in a first direction 222 (including but not limited to a counterclockwise direction); as a result, the end portions 218 of the rotary rod 204 move relative to the bracket 216 from point A to point B in a linked motion direction 226 (including but not limited to

5

an counterclockwise direction). That is to say, the pivotal pins **214** move along the curved grooves **220** and rotate by a specific angle, respectively. The rotary rod **204** functions as an active component for use in axial rotation, and its rotational angle is controlled with the handle body **208** operated by the user. The handle body **208** and the rotary rod **204** are integrally formed as a unitary structure or connected by a connecting element, but the present invention is not limited thereto.

The sliding elements **212** are disposed on the inner sides of the lateral sides **215** of the bracket **216** by means of a pair of sliding grooves **228** thereon, respectively. An engaging guiding groove **230** is disposed on each of the sliding elements **212** for snap-engagement with a corresponding one of the pivotal pins **214** of the rotary rod **204**. Hence, the pivotal pins **214** are not only coupled to the rotary rod **204** and the bracket **216** and engaged with the curved grooves, but also snap-engaged with the sliding elements **212** as soon as the sliding elements **212** are positioned at the bracket **216**.

The engaging guiding groove **230** is of a shape of a linear guiding groove. Given the aforesaid arrangement as well as the joint operation of the pivotal pins **214**, the curved grooves **220**, and the engaging guiding groove **230**, once the user starts to operate the handle body **208** in the first direction **222** (including but not limited to a counterclockwise direction), the sliding elements **212** will move in a first sliding element direction **280** (including but not limited to a rightward horizontal direction). If the user operates the handle body **208** in a second direction **284** (including but not limited to a clockwise direction), the sliding elements **212** will move in a second sliding element direction **288** (including but not limited to a leftward horizontal direction). The aforesaid movement of the sliding elements is enabled mainly by the appropriate design of the intersections of the linear guiding groove **230** and the curved groove **220** to thereby effectuate leftward and rightward motion.

FIG. 2 shows a pair of supporting stands **232** fixed to the first circuit board **104** and a pair of supporting stand guiding grooves **236** disposed on the bracket **216**, wherein the supporting stand guiding groove **236** has a specific inclination. As described above, the pivotal pins **214** come into snap-engagement with the sliding elements **212** as soon as the sliding elements **212** are positioned at the bracket **216**; hence, if the sliding elements move rightward and horizontally, the sliding elements **212** will be pushed upward to thereby abut against the bracket **216** and the second circuit board **108** because of the oblique supporting stand guiding groove **236** and the supporting stands **232** fixed to the first circuit board **104**; as a result, the bracket **216** and the second circuit board **108** move vertically upward. If the sliding elements **212** move leftward and horizontally, the sliding elements **212** will drive the second circuit board **108** and the second assembly **124** to move downward because of the oblique supporting stand guiding grooves **236** and the supporting stands **232** fixed to the first circuit board **104**; as a result, the bracket **216** and the second circuit board **108** move vertically downward. That is to say, given appropriate design, the rotation of the rotary rod **204** drives the bracket **216** and the second circuit board **108** to move vertically, that is, upward and downward.

FIG. 2 shows guide pins **240**, **244** disposed on the first circuit board **104**. The guide pins **240**, **244** operate in conjunction with holes **248**, **252** on the bracket **216** with a view to providing a preliminary guide before the male connector **140** and the female connector **144** are connected together, so as to prevent misalignment-induced damage which might otherwise occur as a result of the preliminary connection of the male connector **140** and the female connector **144**.

6

As described above, the rotary rod **204** and the bracket **216** are linked together in accordance with an axis of motion, whereas the pivotal pins **214** move along the curved grooves **220**. Due to a continuum of intersections of the linear guiding groove **230** and the curved groove **220**, the sliding elements **212** are slidably disposed inside the bracket **216** and move horizontally. However, the bracket **216** and the second circuit board **108** move in a vertical direction, and thus the connectors are less likely to get damaged because of offset and misalignment.

Referring to FIG. 3 and FIG. 4, there are perspective views of a preferred embodiment of the present invention, illustrating its use and its course of motion and related details. Referring to FIG. 1 through FIG. 3, the aforesaid assemblies are mounted on the first circuit board **104** to implement an electronic device **300** (see FIG. 3). The electronic device **300** has other assemblies, such as a casing (not shown) and a fan (not shown). The aforesaid assemblies are part of a conventional electronic device assembly and thus are not described herein in detail for the sake of brevity. Referring to FIG. 3, the pivotal pins **214** are located at point A, that is, the starting point, and thus the male connector **140** and the female connector **144** are in a coupled state; meanwhile, the bracket **216** and the second circuit board **108** are flatly positioned on the first circuit board **104**. Once the user starts to operate the handle body **208** and actuate the rotary rod **204**, the pivotal pins **214** will move toward point B in a third direction **308**, that is, a destination point.

Referring to FIG. 1 through FIG. 4, after the user has driven the rotary rod **204** to rotate, the pivotal pins **214** move along the curved grooves **220** from point A to point B, respectively; that is to say, the pivotal pins **214** move along the curved grooves **220** and rotate by a specific angle, respectively. Hence, the male connector **140** and the female connector **144** are released from the initial coupled state in a vertical manner. The aforesaid assemblies undergo coordinated operation, such that the bracket **216** moves vertically and upward because of the rotation of the rotary rod **204**; meanwhile, the bracket **216** and the second circuit board **108** move upward vertically relative to the first circuit board **104**.

Similarly, if the user operates the handle body **208** once again and actuates the rotary rod **204**, the pivotal pins **214** will move from point B to point A in a fourth direction **408**; meanwhile, the bracket **216** and the second circuit board **108** move downward and vertically relative to the first circuit board **104**, such that the male connector **140** and the female connector **144** return to the coupling state once again in a vertical manner.

In conclusion, in an embodiment of the present invention, the male connector **140** and the female connector **144** are connected together and disconnected from each other by being vertically lifted and lowered, not only to prevent the pins from being damaged because of misalignment of the male connector **140** and the female connector **144**, but also to extend the service life of the connectors. An embodiment of the present invention not only meets the tool-less requirement, but also greatly reduces the forces required for the connection and disconnection of connectors and thereby prevents other circuit boards and connectors from being damaged during the installation process thereof.

In another aspect, from the perspective of the connection and disconnection of a circuit board and another circuit board, an embodiment of the present invention enables the labor-saving plugging/unplugging of connectors and releases a mating force otherwise applied to a connector beforehand by means of the rotation of a rotary rod and related lever opera-

tions, thereby rendering it easy to plug and unplug a male connector and a female connector.

The foregoing preferred embodiments are provided to illustrate and disclose the technical features of the present invention, and are not intended to be restrictive of the scope of the present invention. Hence, all equivalent variations or modifications made to the foregoing embodiments without departing from the spirit embodied in the disclosure of the present invention should fall within the scope of the present invention as set forth in the appended claims.

What is claimed is:

1. A circuit board assembly, comprising:

a first circuit board;

a second circuit board;

a bracket for supporting the second circuit board, wherein the bracket has a pair of lateral sides each having thereon a curved groove and a sliding groove;

an interconnect apparatus for a connection and a disconnection of the first circuit board to the second circuit board, wherein the interconnect apparatus comprises a first connector disposed on the first circuit board and a second connector disposed on the second circuit board so as to effectuate the connection and disconnection of the first circuit board to the second circuit board;

a bracket lifting and lowering apparatus for vertically lifting and lowering the bracket such that after the connection the second connector is vertically disconnected from the first connector and after the disconnection the second connector is vertically connected to the first connector, wherein the bracket lifting and lowering apparatus comprises:

a rotary rod having a pair of end portions each provided with a pivotal pin, and

a pair of sliding elements slidably disposed in the sliding grooves, respectively, the sliding elements each having thereon a linear guiding groove and a supporting stand guiding groove of a specific inclination, wherein the rotary rod is pivotally coupled to the bracket by the pivotal pins and the curved grooves, wherein the sliding elements are engaged with the bracket through the pivotal pins and the linear guiding grooves; and

a pair of supporting stands fixed to the first circuit board and slidably disposed in the supporting stand guiding grooves, respectively.

2. The circuit board assembly of claim 1, wherein, in response to rotation of the rotary rod in a first direction, the pivotal pins follow a continuum of intersections of each said linear guiding groove and a corresponding one of the curved grooves to thereby allow the sliding elements to undergo a horizontal displacement, wherein the horizontal displacement of the sliding elements is accompanied by a vertical displacement of the bracket and the second circuit board because of joint operation of engagement of the sliding elements with the bracket, the supporting stands fixed to the first circuit board, and the supporting stand sliding grooves of a specific inclination.

3. The circuit board assembly of claim 1, wherein the first connector and the second connector are one selected from the group consisting of an QuickPath Interconnect (QPI) and a HyperTransport (HT) interconnect, wherein a first assembly is disposed on the first circuit board and is one selected from the group consisting of a CPU and a memory, wherein a second assembly is disposed on the second circuit board and is one selected from the group consisting of a CPU and a memory.

4. An electronic device, comprising:

a casing;

a circuit board assembly, comprising:

a first circuit board;

a second circuit board;

a bracket for supporting the second circuit board;

an interconnect apparatus for a connection and a disconnection of the first circuit board and the second circuit board, the interconnect apparatus comprising a first connector disposed on the first circuit board and a second connector disposed on the second circuit board for a connection or a disconnection thereof;

a bracket lifting and lowering apparatus for vertically lifting and lowering the bracket such that after the connection the second connector is vertically disconnected from the first connector and after the disconnection the second connector is vertically connected to the first connector, wherein the bracket has a pair of lateral sides each having thereon a curved groove and a sliding groove, wherein the bracket lifting and lowering apparatus comprises:

a rotary rod having a pair of end portions each having thereon a pivotal pin, and

a pair of sliding elements slidably disposed in the sliding grooves, respectively, the sliding elements each having thereon a linear guiding groove and a supporting stand guiding groove of a specific inclination, wherein the rotary rod is pivotally coupled to the bracket by the pivotal pins and the curved grooves, wherein the sliding elements are engaged with the bracket by the pivotal pins and the linear guiding grooves; and

a pair of supporting stands fixed to the first circuit board and slidably disposed in the supporting stand guiding grooves, respectively.

5. The electronic device of claim 4, wherein, in response to rotation of the rotary rod in a first direction, the pivotal pins follow a continuum of intersections of each said the linear guiding groove and a corresponding one of the curved grooves to thereby allow the sliding elements to undergo a horizontal displacement, wherein the horizontal displacement of the sliding elements is accompanied by a vertical displacement of the bracket and the second circuit board because of joint operation of engagement of the sliding elements with the bracket, the supporting stands fixed to the first circuit board, and the supporting stand sliding grooves of a specific inclination.

6. A lifting and lowering apparatus applicable to a circuit board assembly, the circuit board assembly comprising a first circuit board, a second circuit board, an interconnect apparatus for a connection and a disconnection of the first circuit board and the second circuit board, the interconnect apparatus comprising a first connector disposed on the first circuit board and a second connector disposed on the second circuit board for a connection or a disconnection thereof, and a bracket for supporting the second circuit board, the bracket having a pair of lateral sides, the lateral sides each having thereon a curved groove and a sliding groove, the lifting and lowering apparatus comprising:

a rotary rod having a pair of end portions each provided with a pivotal pin;

a pair of sliding elements slidably disposed in the sliding grooves, respectively, the sliding elements each having thereon a linear guiding groove and a supporting stand guiding groove of a specific inclination, wherein the rotary rod is pivotally coupled to the bracket by the pivotal pins and the curved grooves, wherein the sliding

elements are engaged with the bracket by the pivotal pins and the linear guiding grooves; and
a pair of supporting stands fixed to the first circuit board and slidably disposed in the supporting stand guiding grooves, respectively;

wherein, in response to rotation of the rotary rod in a first direction, the pivotal pins follow a continuum of intersections of each said linear guiding groove and a corresponding one of the curved grooves to thereby allow the sliding elements to undergo a horizontal displacement and allow the bracket to undergo a vertical displacement.

7. The lifting and lowering apparatus of claim 6, wherein the lifting and lowering apparatus for vertically lifting and lowering the bracket and the second circuit board such that after the connection the second connector is vertically disconnected from the first connector and after the disconnection the second connector is vertically connected to the first connector.

* * * * *
